

PROCESSING OF CORIANDER

Introduction

Coriander (*Coriandrum sativum* L.) is an annual herb with branching stems and small white, pinkish flowers that grows to a height of about 90cm. It is a member of the same family as carrots and parsley (Umbelliferae) and is native to the Mediterranean and Middle East. Coriander, which is also known as Chinese parsley and cilantro, is grown for its seeds and leaves, both of which are used in a range of dishes. Coriander requires well drained soils and plenty of warmth and sunshine. It is grown as a crop in India, Russia, Brazil, South America, North America and Holland.

Uses

The seeds are tiny globes, about the same size as peppercorns, which are a pale creamy brown colour. The seeds from Indian coriander tend to be elongated while the seeds from European coriander are more round in shape (see figure 1). They are dried and ground and included in curry powder and garam masala powder in Indian cooking. Quite frequently ground coriander and cumin are used in the same dish.

The leaves are used as a fresh green vegetable or salad leaf. Coriander seed oil is used for a range of medicinal applications. It has antibacterial properties and is used in treatments for colic, neuralgia and rheumatism. It has industrial applications in pharmaceutical applications and tobacco where it is used to counteract unpleasant odours.

Harvesting

Harvesting at the correct stage of ripeness is essential for the coriander seed to have a full aroma. Under-ripe coriander seeds have an unpleasant flavour and lack the distinctive spicy aroma and over-ripe seeds (after about 90 days from planting) tend to shatter which reduces the yield. Since ripening is progressive on the plant, harvesting should take place when between half and two thirds of the seeds are ripe. To minimise breakage, the plants should be cut during the early morning while the dew is on the plant or in the late evening. After harvest the seed is dried and stored for later use.

Drying

The typical aroma and flavour of coriander seed is not fully developed until it is completely dry. Usually the whole plants are spread out in the sun to dry. They are left to wither for two days until the moisture content is about 18%. They are then threshed to remove the seeds which are further dried to a final moisture content of 9%. The second drying stage should be in the shade to prevent over-heating of the seeds. The drying time depends on the climate.

In some countries artificial dryers are used to dry the seed. It is important to ensure that the temperature of drying ovens does not exceed 100°C as this reduces the levels of volatile oils. The clean seed should be stored in bags or closed containers.

Essential oil extraction

The ground seeds can be used for the extraction of essential oils. The seed is ground immediately prior to distillation to increase the yield of oil and reduce the distillation time. The essential oil content varies from 0.1-1.5% and contains a range of different essential oils. For more information on how to distil essential oils, see the Practical Action Technical Brief.

Equipment suppliers

This is a selective list of suppliers of equipment and does not imply endorsement by Practical Action.

This website includes lists of companies in India who supply food processing equipment.

Practical Action is a development charity with a difference. We know the simplest ideas can have the most profound, life-changing effect on poor people across the world. For over 40 years, we have been working closely with some of the world's poorest people - using simple technology to fight poverty and transform their lives for the better. We currently work in 15 countries in Africa, South Asia and Latin America.
